The study of symmetries represents a **fundamental point related to the analysis of integrability of differential equations**, since this invariance property may be used to achieve partial or complete integration of such equations.

A standard method for finding solutions of a PDE can be implemented using Lie symmetries: **each Lie symmetry leads to a similarity reduction for the PDE** which allow us to reduce by one the number of variables.

In this work, we are concerned with the analysis of the Lax pair, considered as a proof of the integrability of a PDE. As mentioned, Lie symmetries for the PDE are very popular in literature, but the symmetry analysis for the Lax pair is often less studied.

This approach has the benefit that the reduction associated to each symmetry of the Lax pair provides both the reduced equations and the reduced spectral problem.

Multi-component NLS Equation in 2 + 1

An integrable multi-component nonlinear Schrödinger equation in 2 + 1 dimensions is presented:

$$\begin{aligned} i\vec{\alpha}_t + \vec{\alpha}_{xx} + 2m_x \vec{\alpha} &= 0, & -i\vec{\alpha}_t^\dagger + \vec{\alpha}_{xx}^\dagger + 2m_x \vec{\alpha}^\dagger &= 0, \\ \left(m_y + \vec{\alpha} \vec{\alpha}^\dagger\right)_x &= 0, \end{aligned} \quad (1)$$

where $\vec{\alpha}(x, y, t) = (\alpha_1(x, y, t), \alpha_2(x, y, t))^T$ and $\vec{\alpha}^\dagger$ is the complex conjugate of $\vec{\alpha}$. $m(x, y, t)$ is a real scalar function related to the probability density $\vec{\alpha} \vec{\alpha}^\dagger$.

The three-component Lax pair for (1), and its complex conjugate, has the following form:

$$\begin{aligned}\psi_y &= -\alpha_1^\dagger \chi - \alpha_2^\dagger \rho, & \psi_t &= -\psi_{xx} - 2m_x \psi \\ \chi_x &= -\alpha_1 \psi, & \chi_t &= -(\alpha_1)_x \psi + \alpha_1 \psi_x \\ \rho_x &= -\alpha_2 \psi, & \rho_t &= -(\alpha_2)_x \psi + \alpha_2 \psi_x\end{aligned}\quad (2)$$

where the eigenvector of the Lax Pair is defined by
 $\vec{\Psi}(x, y, t) = (\psi(x, y, t), \chi(x, y, t), \rho(x, y, t))^T$.

Note that no spectral parameter appears in this Lax Pair.

The infinitesimal generator of the group of the previous transformations is given by the vector field

$$\begin{aligned} X = & \xi_1 \frac{\partial}{\partial x} + \xi_2 \frac{\partial}{\partial y} + \xi_3 \frac{\partial}{\partial t} + \eta_1 \frac{\partial}{\partial u} + \eta_2 \frac{\partial}{\partial \omega} + \eta_3 \frac{\partial}{\partial m} \\ & + \phi_1 \frac{\partial}{\partial \psi} + \phi_2 \frac{\partial}{\partial \chi} + \phi_3 \frac{\partial}{\partial \rho} \end{aligned} \quad (4)$$

This infinitesimal transformation induces a well known one in the derivatives of the fields. This procedure, applied to (2), leads to an overdetermined system of PDEs for the infinitesimals, whose solution provides the symmetry transformations.

After determining the symmetries, the similarity reduction for each symmetry may be performed, which allows to reduce by one the number of independent variables.

Similarity reductions can be computed from the analysis of invariant solutions, obtained by solving the characteristic system

$$\frac{dx}{\xi_1} = \frac{dy}{\xi_2} = \frac{dt}{\xi_3} = \frac{d\alpha_1}{\eta_1} = \frac{d\alpha_2}{\eta_2} = \frac{dm}{\eta_3} = \frac{d\psi}{\phi_1} = \frac{d\chi}{\phi_2} = \frac{d\rho}{\phi_3} \quad (7)$$

In the following, we will deal with the invariant solutions

	Original variables	New reduced variables
Independent variables	x, y, t	p, q
Fields	$\alpha_1(x, y, t), \alpha_2(x, y, t), m(x, y, t)$	$F(p, q), H(p, q), N(p, q)$
Eigenfunctions	$\psi(x, y, t), \chi(x, y, t), \rho(x, y, t)$	$\Phi(p, q), \Sigma(p, q), \Omega(p, q),$
